Abstract

We point out that the lower bound on m_t from the CP violation parameter ϵ_K has increased considerably. Using Wolfenstein parametrization of the CKM matrix we derive an analytic expression for this bound as a function of $|V_{cb}|$, $|V_{ub}/V_{cb}|$ and the non-perturbative parameter B_K . For $B_K \leq 0.80$, $|V_{cb}| \leq 0.040$ and $|V_{ub}/V_{cb}| \leq 0.10$ we find $m_t > 130 \text{ GeV}$. However, for $B_K \leq 0.70$, $|V_{cb}| \leq 0.038$ and $|V_{ub}/V_{cb}| \leq 0.08$ the bound is raised to $m_t > 205 \text{ GeV}$. The lower bound on m_t from $B^o - \bar{B}^o$ mixing is also reconsidered.

Ten years ago Ginsparg, Glashow and Wise [1] calculated a lower bound on the top quark mass (m_t) by analysing the CP violation parameter ϵ_K in the standard model. Subsequently a more detailed analysis has been done by Słominski, Steger and the present author [2]. The lower bound on m_t considered in [1, 2] takes the general form

$$m_t \geq F(|V_{cb}|, |V_{ub}/V_{cb}|, B_K) \quad (1)$$

where V_{ij} are the elements of the Cabibbo-Kobayashi-Maskawa matrix and B_K is a non-perturbative parameter to be specified below. The function F increases with decreasing $|V_{cb}|$, $|V_{ub}/V_{cb}|$ and B_K .

In 1983 the values of $|V_{cb}|$, $|V_{ub}/V_{cb}|$ and of B_K have been poorly known and no useful bound on m_t could be obtained. During the last ten years the experimental determinations of $|V_{cb}|$ and $|V_{ub}/V_{cb}|$ have been considerably improved and some progress has been made in calculating B_K . It is of interest then to reanalyse the bound in view of these developments and in view of the possibility that the top quark could be discovered soon.

In fact the present “best” values for $|V_{cb}|$, $|V_{ub}/V_{cb}|$ and B_K are substantially lower than the corresponding values of 1983. Consequently the lower bound on m_t from ϵ_K can be considerably improved.

We note:

- The new experimental results on exclusive semi-leptonic B -decays [3] combined with the increased B -meson life-time measured at LEP and by CDF at Tevatron $\tau_B = 1.49 \pm 0.03 ps$ [4] give with the help of the Heavy Quark Effective Theory [5, 6]

$$\kappa \equiv |V_{cb}| \left(\frac{\tau_B}{1.5 ps} \right)^{1/2} = 0.038 \pm 0.006 \quad (2)$$

Similar results can be found in [7, 8]. This value should be compared with $|V_{cb}| \approx 0.05$ of 1983.

- The most recent determinations of $|V_{ub}/V_{cb}|$ give typically [9, 10]

$$\left| \frac{V_{ub}}{V_{cb}} \right| = 0.08 \pm 0.02 \quad (3)$$

- The extensive calculations of B_K using lattice gauge theories, $1/N$ expansion and QCD sum rules of various sorts, give consistently $B_K < 1$. The range

$$B_K = 0.7 \pm 0.2 \quad (4)$$

is a good representaton of the $1/N$ [11], lattice results [12] and QCD sum rules results [13]. The QCD hadron duality approach gives somewhat lower values $B_K = 0.4 \pm 0.1$ [14]. Finally the leading term in the chiral perturbation theory in the strict $SU(3)$ limit gives $B_K = 1/3$ [15].

- The next-to-leading QCD corrections to the QCD factor η_2 (see below) [16] decrease its value from 0.62 to 0.57 making the lower bound on m_t somewhat stronger.

In the coming years further improvements on $|V_{cb}|$, $|V_{ub}/V_{cb}|$ and B_K are to be expected. It is then of interest to reanalyse the bound (1) as a function of these three parameters. As a byproduct of our analysis we will derive an approximate analytic expression for the function F . Our analysis complements the numerous analyses of the unitarity triangle where the lower bound on m_t has not been addressed.

Formulated in terms of the Wolfenstein parameters λ, A, ρ and η the lower bound on m_t arises from the measured value of ϵ_K roughly as follows. The usual box diagram calculation together with the experimental value for ϵ_K specifies the following hyperbola in the $(\rho, \eta > 0)$ plane [17, 18]

$$\eta \left[(1 - \rho) A^2 \eta_2 S(x_t) + \lambda^{-4} P_0 \right] A^2 B_K = 0.223 \quad (5)$$

Here

$$A \equiv |V_{cb}| / \lambda^2 \quad \lambda = |V_{us}| = 0.22 \quad (6)$$

$$P_0 = \eta_3 S(x_c, x_t) - \eta_1 x_c \quad (7)$$

$$S(x_c, x_t) = x_c \left[\ln \frac{x_t}{x_c} - \frac{3x_t}{4(1-x_t)} \left(1 + \frac{x_t}{1-x_t} \ln x_t \right) \right] \quad (8)$$

$$S(x_t) = x_t \left[\frac{1}{4} + \frac{9}{4} \frac{1}{(1-x_t)} - \frac{3}{2} \frac{1}{(1-x_t)^2} \right] + \frac{3}{2} \left[\frac{x_t}{x_t-1} \right]^3 \ln x_t \quad (9)$$

where $x_i = m_i^2/M_W^2$. B_K is the renormalization group invariant non-perturbative parameter describing the size of $\langle \bar{K}^0 | (\bar{s}d)_{V-A}(\bar{s}d)_{V-A} | K^0 \rangle$ and η_i represent QCD corrections to the box diagrams.

On the other hand the experimental value of $|V_{ub}/V_{cb}|$ determines a circle of the radius

$$R_b = \frac{1}{\lambda} \left| \frac{V_{ub}}{V_{cb}} \right| = [\rho^2 + \eta^2]^{1/2} \quad (10)$$

centered at $(\rho, \eta) = (0, 0)$. The hyperbola (5) intersects the circle (10) in two points, one for $\rho < 0$ and the other for $\rho > 0$. With decreasing A (or $|V_{cb}|$), B_K and m_t , the hyperbola (5) moves away from the origin of the (ρ, η) plane. For sufficiently low A, B_K, m_t and R_b the hyperbola and the circle only touch each other. This way a lower bound for m_t as a function of B_K, V_{cb} and $|V_{ub}/V_{cb}|$ can be found.

For the numerical evaluation of this bound it is better to use the exact standard parametrization of the CKM matrix [19] and a more accurate formula for ϵ_K given e.g. in (5.22) of ref.[18]. However, the formulation given above allows to find a simple analytic expression for $(m_t)_{min}$ which to an accuracy better than 2% reproduces the results of a more elaborate analysis.

In order to find a formula for $(m_t)_{min}$ which is simple and accurate we proceed as follows. We note first that in the “exact” numerical analysis which uses the standard parametrization of the CKM matrix the lower bound on m_t corresponds to $\sin\delta = 1$ i.e. to $\rho = 0$. Equations (5) and (10) being approximations give generally $(m_t)_{min}$ at a small negative value of ρ rather than at $\rho = 0$. In spite of this the most efficient strategy is to set $\rho = 0$ in (5) and (10) to find the following condition for $(m_t)_{min}$:

$$S(x_t) = \frac{1}{A^2 \eta_2} \left[\frac{0.223}{A^2 B_K R_b} - \frac{P_0}{\lambda^4} \right] \quad (11)$$

We use next [18]

$$S(x_t) = 0.784 \ x_t^{0.76} \quad (12)$$

which is an excellent approximation of (9) in the range $100 \leq m_t \leq 300 \text{ GeV}$. In the same range of m_t , P_0 takes the values $6.25 \cdot 10^{-4} \leq P_0 \leq 7.59 \cdot 10^{-4}$ where we have used $\eta_1 = 0.85, \eta_3 = 0.36$ and $m_c = 1.4 \text{ GeV}$. In view of this weak m_t -dependence compared to (12), P_0 can be approximated by a constant. This constant can be chosen in such a way that the analytic bound reproduces the results of a more accurate numerical analysis as good as possible. $P_0 = 6.25 \cdot 10^{-4}$ turns out to be a good choice.

From (11) and (12) we finally obtain the analytic lower bound on m_t :

$$(m_t)_{min} = \left[\frac{1}{0.784} \left(\frac{1}{A^2 \eta_2} \left[\frac{0.223}{A^2 B_K R_b} - \frac{1}{\lambda^4} \right] \right) \right]^{0.658} \quad (13)$$

which is the main formula of this letter. To this end we have set $\eta_2 = 0.57$ [16]. This QCD factor is so defined that the resulting m_t is the current top quark mass normalized at $\mu = m_t$. The m_t dependence of η_2 can be neglected. Formula (13) together with (6) and (10) gives $(m_t)_{min}$ as a function of $|V_{cb}|$, $|V_{ub}/V_{cb}|$ and B_K . It is evident from (13) that this bound increases with decreasing A (or $|V_{cb}|$), B_K and R_b (or $|V_{ub}/V_{cb}|$). We note a very strong dependence on A . We have checked that in the ranges of $|V_{cb}|$, $|V_{ub}/V_{cb}|$ and B_K used below, our analytic bound gives a very good representation (generally to better than 2% accuracy) of a more elaborate numerical analysis which uses accurate formulae of ref.[18]

In order to get better acquainted with the bound (13) we note that for $0.035 \leq |V_{cb}| \leq 0.043$ and $0.06 \leq |V_{ub}/V_{cb}| \leq 0.10$ we have $0.72 \leq A \leq 0.89$ and $0.27 \leq R_b \leq 0.45$ respectively. Consequently for B_K given in (4) we find $3.1 \leq 1/(A^2 B_K R_b) \leq 14.3$. For central values $B_K = 0.7$, $|V_{ub}/V_{cb}| = 0.08$ and $|V_{cb}| = 0.038$ we have $1/(A^2 B_K R_b) = 6.5$.

The bound in (13) is very interesting as it results from a different sector of the standard model than the corresponding bound on m_t obtained from high precision electroweak studies at LEP and Tevatron. Whereas the fate of the latter bounds depends sensitively on the precise measurements of $M_W, \Gamma_Z, \sin^2 \Theta_W$, etc., the lower bound in (13) is subject to our knowledge of $|V_{cb}|$, $|V_{ub}/V_{cb}|$ and B_K .

In figs. 1-3 we plot $(m_t)_{min}$ as a function of $|V_{cb}|$ for different values of B_K and $|V_{ub}/V_{cb}|$. We have set $M_W = 80. GeV$. These plots are self explanatory. Therefore we only make a few comments.

We note that for $B_K \leq 0.5$ the lowest value of m_t consistent with the observed CP violation is generally substantially larger than 200 GeV. For B_K in the range (4), the values of $(m_t)_{min}$ are compatible with the restrictions on m_t ($150 \pm 40 GeV$) coming from electroweak studies, although for $|V_{ub}/V_{cb}| \leq 0.08$, $|V_{cb}| \leq 0.038$ and $B_K \leq 0.7$ again $(m_t)_{min} > 200 GeV$ is favoured. In such a situation a discovery of the top quark with $m_t \approx 150 GeV$ would certainly require new positive contributions to ϵ_K in order to lower the bound on m_t coming from the observed CP violation. Charged Higgs exchanges and/or various supersymmetry contributions to ϵ_K would be the prime candidates but such an analysis is beyond the scope of this letter.

It is interesting to compare these bounds with those which can be obtained from

by the parameter $x_d = \Delta M/\Gamma_B$ determines in the (ρ, η) plane a circle centered at $(\rho, \eta) = (1, 0)$ and having the radius

$$R_t = \frac{1}{\lambda} \left| \frac{V_{td}}{V_{cb}} \right| = \left[(1 - \rho)^2 + \eta^2 \right]^{1/2} \quad (14)$$

Using the usual formulae for box diagrams with top quark exchanges [18] it is straightforward to find the value of m_t consistent with x_d as a function of R_t , the B -meson decay constant F_B , the parameter B_B analogous to B_K and κ of (2). Defining

$$r \equiv \left[\sqrt{\frac{x_d}{0.67}} \left[\frac{200 \text{ MeV}}{F_B \sqrt{B_B}} \right] \left[\frac{0.038}{\kappa} \right] \sqrt{\frac{0.55}{\eta_B}} \right]^{1.32} \quad (15)$$

we find

$$m_t = r R_t^{-1.32} 179.4 \text{ GeV} \quad (16)$$

Here η_B is the QCD factor analogous to η_2 and calculated to be $\eta_B = 0.55$ [16]. Since (10) and (14) must be consistent with each other the lower bound on m_t from $B^o - \bar{B}^o$ mixing without any constraint from ϵ_K is found by setting $\eta = 0$ and $\rho = -R_b$ which implies $R_t = 1 + R_b$. This gives then

$$(m_t)_{min} = \begin{cases} r \cdot 110 \text{ GeV} & |V_{ub}/V_{cb}| = 0.10 \\ r \cdot 120 \text{ GeV} & |V_{ub}/V_{cb}| = 0.08 \\ r \cdot 131 \text{ GeV} & |V_{ub}/V_{cb}| = 0.06 \end{cases} \quad (17)$$

We observe that this bound depends much weaker on $|V_{ub}/V_{cb}|$ than the bound on ϵ_K given in (13).

The fate of the lower bound from $B^o - \bar{B}^o$ mixing depends on the ratio r in (15). With $x_d = 0.67 \pm 0.10$ [20], $\kappa = 0.038 \pm 0.006$ and $F_B \sqrt{B_B} = 200 \pm 40 \text{ MeV}$ [21] one has the range $0.58 \leq r \leq 1.85$ i.e. a large uncertainty. For central values of the parameters the lower bound from $B^o - \bar{B}^o$ mixing is generally weaker than from ϵ_K . It should however be emphasized that the lower bound from $B^o - \bar{B}^o$ mixing in 1993 is substantially higher than the bounds found in the 80's [22]. This is primarily due to the values of κ and η_B which were substantially higher in those days. For instance with $V_{cb} \simeq 0.05$ and $\tau_B \simeq 1.2 \text{ ps}$ one had $\kappa \simeq 0.046$. Taking in addition $\eta_B \simeq 0.85$ used in older analyses decreases the lower bound on m_t by a factor of 1.7. This factor is somewhat reduced by the higher values of F_B found at present.

In this letter we have emphasized that the lower bounds on m_t coming from ϵ_K and $B^o - \bar{B}^o$ mixing are much more solid than the best ones. Interestingly,

ϵ_K appears to be higher than the estimates of m_t from the precision electroweak studies at LEP. Are these some hints for the physics beyond the standard model? In order to answer this question continuous efforts should be made to decrease the uncertainties in $|V_{cb}|$, $|V_{ub}/V_{cb}|$, B_K and F_B . It will be exciting to watch in the coming years the developments in B -decays, in electroweak studies and in particular in top quark searches. We hope that figs. 1-3 and the analytic lower bounds on m_t derived here will help to see quickly where we stand.

I would like to thank Gerhard Buchalla and Gaby Ostermaier for a careful reading of the manuscript. I also thank Dean Karlen and Sheldon Stone for e-mail messages.
